# Basics 1

- ▶ The Helmholtz equation is

$$\nabla^2 \psi + k^2 n^2(x, y, z) \psi = 0$$

where  $k = \frac{2\pi}{\lambda}$  and  $n(x, y, z)$  is the refractive index at the given co-ordinates.

- ▶ Approximate the wavefunction with plane wave and oscillating parts,

$$\psi(x, y, z) = u(x, y, z) \exp(-ikz)$$

## Basics 2

- ▶ Substituting this in the Helmholtz equation and neglecting the derivative of  $u$  along the direction of propagation, we get the following equation.

$$-2ik \frac{\partial}{\partial z} u + \left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) u + k^2(n^2 - 1) = 0$$

- ▶ Define <sup>1</sup>  $a = \frac{-i}{2k}$  and  $F(x, y, z) = \frac{-i}{2k}(n^2(x, y, z) - 1)$
- ▶ The PDE can now be written as

$$\frac{\partial u}{\partial z} = a \left( \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right) + F(x, y, z) u$$

## Laplacian operator, 1D

- ▶ For a function  $f$  defined on a discrete grid, we can approximate the value of the function  $f$  on the points  $x_{i\pm 1}$ , using the value of  $f$  at  $x_i$  using Taylor series.

$$f(x_{i\pm 1}) = f(x_i) \pm hf'(x_i) + \frac{h^2}{2}f''(x_i) + O(h^3)$$

- ▶ The second derivative can thus be approximated as

$$f''(x_i) \approx \frac{f_{i+1} - 2f_i + f_{i-1}}{h^2}$$

## Laplacian operator, 1D

- As per the last approximation, we can use the following matrix operator to calculate the laplacian in 1D.

$$A = \frac{1}{h^2} \begin{bmatrix} -2 & 1 & & & \\ 1 & -2 & 1 & & \\ & \ddots & \ddots & \ddots & \\ & & 1 & -2 & 1 \\ & & & 1 & -2 \end{bmatrix}$$

## Laplacian operator, 2D

- ▶ The discrete laplacian operator in 2D can be derived in a method similar to the 1D case. In 2 dimensions, the second derivate can be approximated as

$$f''(x_{i,j}) \approx \frac{f_{i+1,j} - 2f_{i,j} + f_{i-1,j}}{h_x^2} + \frac{f_{i,j+1} - 2f_{i,j} + f_{i,j-1}}{h_y^2}$$

## Laplacian operator, 2D

- ▶ As per the last approximation, we can use the following block matrix operator to calculate the laplacian in 2D.

$$A = \begin{bmatrix} A_{xy} & I_y & & & \\ I_y & A_{xy} & I_y & & \\ & & \ddots & \ddots & \ddots \\ & & & I_y & A_{xy} & I_y \\ & & & & I_y & A_{xy} \end{bmatrix}$$

- ▶ where  $I_y$  is a diagonal matrix with all entries set to  $\frac{1}{h_y^2}$

## Laplacian operator, 2D

► And

$$A_{xy} = \begin{bmatrix} \left\{ \frac{-2}{h_x^2} + \frac{-2}{h_y^2} \right\} & \frac{1}{h_x^2} & & & \\ \frac{1}{h_x^2} & \left\{ \frac{-2}{h_x^2} + \frac{-2}{h_y^2} \right\} & \frac{1}{h_x^2} & & \\ & \ddots & \ddots & \ddots & \\ & & \frac{1}{h_x^2} & \left\{ \frac{-2}{h_x^2} + \frac{-2}{h_y^2} \right\} & \frac{1}{h_x^2} \\ & & & \frac{1}{h_x^2} & \left\{ \frac{-2}{h_x^2} + \frac{-2}{h_y^2} \right\} \end{bmatrix}$$

## Dirichlet Boundary Conditions

- ▶ Dirichlet boundary conditions are applied which physically translates to the effect that outermost pixels never change in value.
- ▶ With Dirichlet BC conditions, the operator A in 1D looks like :

$$A = \frac{1}{h^2} \begin{bmatrix} 1 & 0 & & & \\ 1 & -2 & 1 & & \\ & \ddots & \ddots & \ddots & \\ & & 1 & -2 & 1 \\ & & & 0 & 1 \end{bmatrix}$$

- ▶ The 2D operator changes similarly.

## Integration schemes in 1D

- ▶ Fuhse et.al. suggested the use of implicit, second order schemes<sup>2</sup> for stability and accuracy.
- ▶ For 1D, Crank-Nicolson method is proposed, the stencil for which is shown below<sup>3</sup>.

Crank-Nicolson:  
2<sup>nd</sup> order accurate in time,  
2<sup>nd</sup> order in space  
Unconditionally stable

- ▶ This reduces the problem to a tridiagonal matrix solve which is trivial to solve.

<sup>2</sup>[Fuh06]

<sup>3</sup>MIT OCW 2.29, Numerical Fluid Mechanics

## Integration schemes in 2D

- ▶ In 2D Fuhse et.al suggested the use of Alternating Direction Implicit<sup>4</sup>.
- ▶ ADI is a 2 step process in which alternates between implicit and explicit derivatives along the two dimensions. Each step now involves a tridiagonal matrix solution.

## Previous work

- ▶ Fuhse et.al. chose IDL to implement the programs.
- ▶ A more accurate version of the aforementioned scheme was implemented by Melchoir et.al.<sup>5</sup> in C++ with a Python front end. Although this was efficient, this implementation scheme involved writing the discretization routines for CN and ADI and thereby locked in the developers to these integration schemes.
- ▶ The schemes are straightforward to implement using the `scipy.sparse` libraries<sup>6</sup>.

# FD vs Multislice

- Multislice is better for free space propagation while FD gives better results for propagation through matter. <sup>7</sup>

<sup>7</sup>[MS17][SO91]

## PETSc overview

- ▶ What is PETSc ?

*PETSc, pronounced PET-see (the S is silent), is a suite of data structures and routines for the scalable (parallel) solution of scientific applications modeled by partial differential equations<sup>8</sup>*

- ▶ Why use PETSc ?

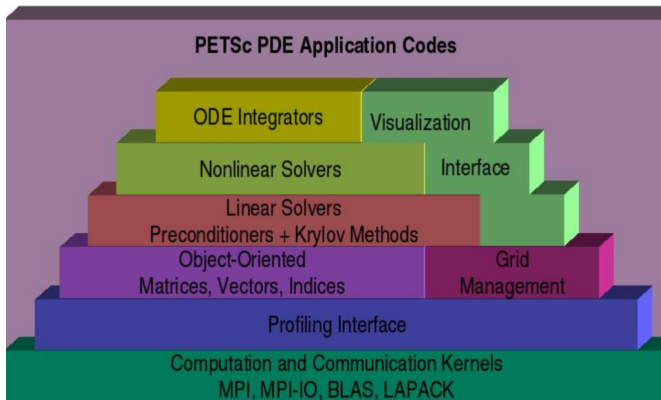

PETSc can solve (in parallel) the linear system we have at hand using a large number of time-stepping integrations schemes, linear solver schemes and preconditioners which can be dynamically configured at runtime! Moreover, higher order finite volume schemes can be explored as well. An optimization library is also included<sup>9</sup>.

---

<sup>8</sup><https://www.mcs.anl.gov/petsc/>

<sup>9</sup>Finite difference is the default method to evaluate the jacobian, but since PETSc is written in C, a source-to-source AD tool like Tapende can be used to give a function that evaluates the jacobian.

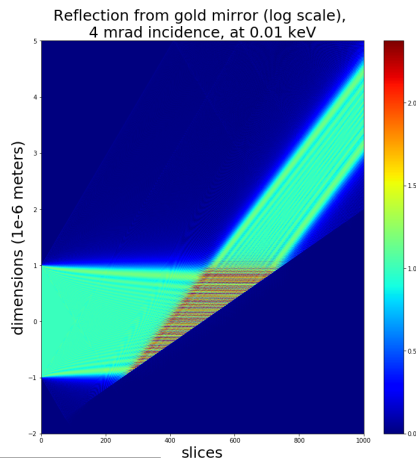

## PETSc architecture<sup>10</sup>

<sup>10</sup><https://www.mcs.anl.gov/petsc/documentation/tutorials/CSCS2010.pdf>

## Results 1D

- Reproduce the plot of x-ray reflectivity from Kenan et.al<sup>11</sup>, using FD/PETSc.
